What is Psychology?

- Psychology is the discipline that studies the pattern of how brain, behaviour, minds and our thoughts are all interrelated. This includes even our body. How each one of these responds to one another respectively.
- It is both an important academic subject and an eminent professional practice.
- It has many sub-disciplines and specialities, allowing practitioners to focus on specific areas of interest within this broad field.

Why Psychology is so significant?

- Developing a more comprehensive and profound comprehension of psychology can assist individuals in gaining valuable insights into their own behaviours and inculcating a deeper understanding of other's emotions and behaviours.
- This helps in self-awareness, improving relationships and promote overall well-being of oneself and others.

DESCRIBE

This is the very first goal of psychology. This goal allows researchers to collect information and then describe what they see and then can learn further. This goal asks “What is happening?” or “What is this individual doing?”

Or about why this is happening and even how to change it.

Here psychologists can distinguish between typical and atypical behaviour.

In order to achieve describing goal, researchers can use various approaches, including natural surveys, observation, case studies, and self- reporting tests.

This is one of the recent and real life example of how some of the vedica scholar are sometimes depressed so there can be various reasons behind their stress. So here a psychologist can use all the techniques and methods to know about their changing behaviour.

Explain

- Why does behaviour occur?
- Under what circumstances it will occur again?
- Psychologist conduct experiments to ensure behaviour.
- What elements influence a person's growth, personality, social behaviour and mental health

Example:- A friend who always gets nervous for an exam.

Worried about failing? Pressure from parents?

PREDICTION

The goal of prediction involves using observed patterns and data to anticipate future behaviors, thoughts, or emotions. Psychologists use various research methods and techniques to identify these patterns, allowing them to make informed predictions about how individuals or groups might behave in specific situations.

Applied Settings: In applied settings, such as clinical psychology or marketing research, prediction plays a significant role

Risk Assessment: Psychologists working in fields like forensic psychology use prediction to assess the risk of certain behaviors, such as criminal recidivism

Identifying Patterns: Psychologists collect and analyze data from experiments, surveys, observations, and other research methods

Statistical Analysis: Psychologists use statistical methods to analyze data and identify correlations or relationships between variables

Generalization: Once psychologists identify patterns in a specific sample, they can generalize their findings to a larger population.

Predictive Models: Psychologists often develop predictive models based on their research findings.

Change/Control

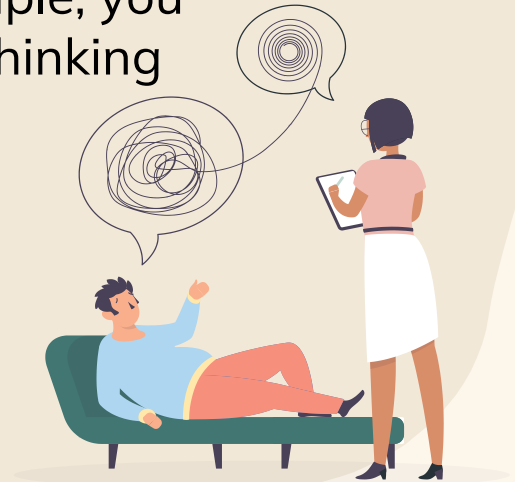

The fourth goal of psychology is to modify behaviors that may be harmful, unproductive, or interfere with daily functioning.

The goal of change asks “How can I stop this habit?” Or “What can I do to be a more generous person?”

This final goal can help bring about positive changes in life, such as decreasing addictive behaviors, reducing depressive symptoms, or improving communication.

Example

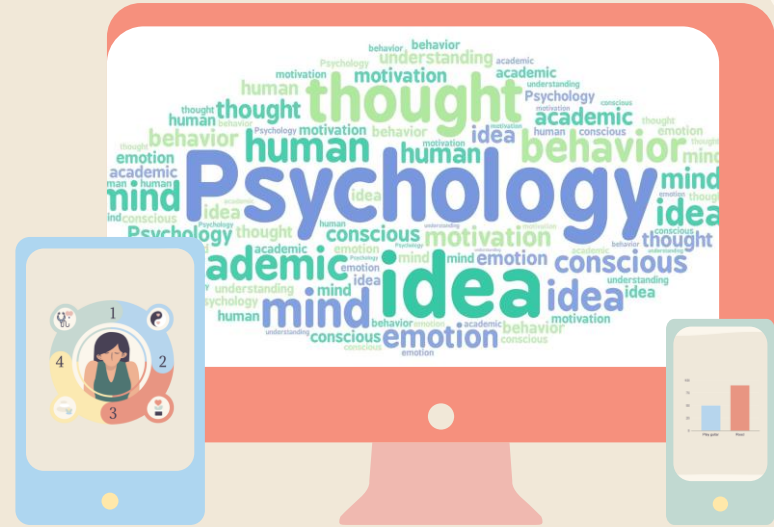

Psychotherapy is an example of this goal in action. In cognitive behavioral therapy (CBT), for example, you identify and change negative and harmful thinking patterns.

Conclusion

The Goals of psychology are multifaceted and continue to evolve with advancement in research and changes in societal needs .

These goals collectively contribute to our understanding of the human mind and behaviour , as well as to the betterment of individuals and society as a whole

Thanks!
